

DIN 02483947

DEXVETIDINE™

(dexmedetomidine hydrochloride sterile injectable solution)

Veterinary Use Only
Sedative and Analgesic
For cats and dogs

DESCRIPTION: Dexvetidine (dexmedetomidine hydrochloride) is a synthetic alpha₂-adrenoreceptor agonist with sedative and analgesic properties. The chemical name is (+)-4-[(S)-α, 2,3-trimethylbenzyl]-imidazole hydrochloride. It is a white, or almost white, crystalline, water soluble substance having a molecular weight of 236.7. The molecular formula is C₁₃H₁₆N₂•HCl and the structural formula is:

Each mL of Dexvetidine contains 0.5 mg dexmedetomidine hydrochloride, 1.6mg methyl parahydroxybenzoate and 0.2 mg propyl parahydroxybenzoate as preservatives, 9.0 mg sodium chloride, sodium hydroxide and hydrochloric acid q.s. for pH adjustment, and water for injection.

INDICATIONS: Dexvetidine is indicated for use as a sedative and analgesic in dogs and cats to facilitate clinical examinations, clinical procedures, minor surgical procedures, and minor dental procedures. Dexvetidine is also indicated for use as a preanesthetic to general anesthesia in dogs and cats.

DOSE AND ADMINISTRATION: It is recommended that dogs and cats be fasted for 12 hours before treatment with Dexvetidine. An eye lubricant should be applied to prevent corneal desiccation that may occur during sedation. Following injection of Dexvetidine, the animal should be allowed to rest quietly for 15 minutes; sedation and analgesia occur within 5 to 15 minutes, with peak effects at 20 to 30 minutes after Dexvetidine.

Dogs: Dexvetidine produces sedation and analgesia when administered intramuscularly (IM) at a dose of 500 mcg/m² or intravenously (IV) at a dose of 375 mcg/m². Doses for preanesthesia are 125 or 375 mcg/m² IM. The choice of preanesthetic dose depends on the duration and severity of the procedure, as well as the anesthetic regime. The following two tables may be used to determine the correct dexmedetomidine hydrochloride dosage.

Note that the mcg/kg dosage decreases as body weight increases.

For example, dogs weighing 2 kg are dosed at 28 mcg/kg dexmedetomidine hydrochloride IV, compared to dogs weighing 80 kg that are dosed at 9 mcg/kg. Due to the small volume of administration, accurate dosing is not possible in dogs weighing less than 2 kg.

Table 1: SEDATION/ANALGESIA DOSE TABLE: Intravenous (IV) and intramuscular (IM) dosing on the basis of body weight.

Sedation/analgesia in dogs				
Dog Weight (kg)	Dexmedetomidine hydrochloride 375 mcg/m ² IV		Dexmedetomidine hydrochloride 500 mcg/m ² IM	
	mcg/kg	Dexvetidine mL	mcg/kg	Dexvetidine mL
	2-3	28.1	0.12	40.0
3-4	25.0	0.15	35.0	0.20
4-5	23.0	0.20	30.0	0.30
5-10	19.6	0.29	25.0	0.40
10-13	16.8	0.38	23.0	0.50
13-15	15.7	0.44	21.0	0.60
15-20	14.6	0.51	20.0	0.70
20-25	13.4	0.60	18.0	0.80
25-30	12.6	0.69	17.0	0.90
30-33	12.0	0.75	16.0	1.00
33-37	11.6	0.81	15.0	1.10
37-45	11.0	0.90	14.5	1.20
45-50	10.5	0.99	14.0	1.30
50-55	10.1	1.06	13.5	1.40
55-60	9.8	1.13	13.0	1.50
60-65	9.5	1.19	12.8	1.60
65-70	9.3	1.26	12.5	1.70
70-80	9.0	1.35	12.3	1.80
>80	8.7	1.42	12.0	1.90

Table 2: PREANESTHESIA DOSE TABLE: Intramuscular (IM) dosing on the basis of body weight.

Preanesthesia in dogs				
Dog Weight (kg)	Dexmedetomidine hydrochloride 125 mcg/m ² IM		Dexmedetomidine hydrochloride 375 mcg/m ² IM	
	mcg/kg	Dexvetidine mL	mcg/kg	Dexvetidine mL
	2-3	9.4	0.04	28.1
3-4	8.3	0.05	25.0	0.15
4-5	7.7	0.07	23.0	0.20
5-10	6.5	0.10	19.6	0.29
10-13	5.6	0.13	16.8	0.38
13-15	5.2	0.15	15.7	0.44
15-20	4.9	0.17	14.6	0.51
20-25	4.5	0.20	13.4	0.60
25-30	4.2	0.23	12.6	0.69
30-33	4.0	0.25	12.0	0.75
33-37	3.9	0.27	11.6	0.81
37-45	3.7	0.30	11.0	0.90
45-50	3.5	0.33	10.5	0.99
50-55	3.4	0.35	10.1	1.06
55-60	3.3	0.38	9.8	1.13
60-65	3.2	0.40	9.5	1.19
65-70	3.1	0.42	9.3	1.26
70-80	3.0	0.45	9.0	1.35
>80	2.9	0.47	8.7	1.42

The use of Dexvetidine as a preanesthetic markedly reduces anesthetic requirements. Injectable induction drug requirements for intubation will be reduced between 30% and 60%, depending on the choice of anesthetic and the Dexvetidine preanesthetic dose. The concentration on inhalation maintenance anesthetic will be reduced between 40% and 60%, depending on the dose of Dexvetidine.

The anesthetic dose should always be titrated against the response of the patient. The choice of anesthetic is left to the discretion of the veterinarian.

Cats: Dexvetidine produces sedation and analgesia when administered IM at a dose of 40 mcg/kg. This dose can also be used as a preanesthetic and has been shown to reduce anesthetic requirements in cats. Injectable anesthetic drug requirements for intubation were reduced up to 49%, depending on the choice of induction drug. The concentration of inhalation maintenance anesthetic was reduced between 35% and 44%, depending on the choice of induction drug. The anesthetic dose should always be titrated against the response of the patient. The following table may be used to determine the correct dexmedetomidine hydrochloride dosage for cats based on body weight.

Table 3: SEDATION/ANALGESIA DOSE TABLE: Intramuscular (IM) dosing on the basis of body weight in cats.

Sedation/analgesia in cats		
Cat Weight (kg)	Dexmedetomidine hydrochloride 40 mcg/kg IM	
	mcg/kg	Dexvetidine mL
	1-2	40
2-3	40	0.2
3-4	40	0.3
4-6	40	0.4
6-7	40	0.5
7-8	40	0.6
8-10	40	0.7

CONTRA-INDICATIONS: Do not use Dexvetidine in dogs or cats with cardiovascular disease, respiratory disorders, liver or kidney diseases, or in conditions of shock, severe debilitation, or stress due to extreme heat, cold or fatigue. Do not use in cases of known hypersensitivity to the active substance or to any of the excipients.

CAUTIONS: Dexmedetomidine hydrochloride in cats has not been evaluated in the presence of other sedatives.

Although not observed in the feline field studies with dexmedetomidine hydrochloride injectable solution, rare cases of delayed pulmonary edema, some resulting in death, have been reported in cats that received dexmedetomidine hydrochloride injectable solution. In these cases, dyspnea due to the delayed onset of pulmonary edema developed up to three days after dexmedetomidine hydrochloride administration.

Dexvetidine should not be administered in the presence of preexisting hypotension, hypoxia, or bradycardia. Due to the pronounced cardiovascular effects of dexmedetomidine hydrochloride injectable solution, only clinically healthy dogs and cats should be treated. Animals should be frequently monitored for cardiovascular function and body temperature during sedation or anesthesia.

Intramuscular atipamezole hydrochloride injectable solution may be routinely used to rapidly reverse the effects of Dexvetidine in dogs. Since analgesic as well as sedative effects will be reversed, pain management may need to be addressed. Atipamezole has not been evaluated as a routine dexmedetomidine reversal agent in cats. In the event of apnea, additional oxygen should be supplied. Administration of atipamezole hydrochloride injectable solution to dogs is warranted when apnea is accompanied by bradycardia and cyanotic mucous membranes.

Anesthetic safety is increased when supplemental oxygen is given by mask or endotracheal tube to cats and dogs anesthetized with intravenous regimes, and this applies to the use of Dexvetidine as well.

A decrease in body temperature is likely to occur during sedation with Dexvetidine unless externally maintained. Once established, hypothermia may persist longer than sedation and analgesia. To prevent hypothermia, treated animals should be kept warm and at a constant temperature during the procedure, and until full recovery.

Nervous or excited animals with high levels of endogenous catecholamines may exhibit a reduced pharmacological response to alpha₂-adrenoreceptor agonists like dexmedetomidine. In agitated animals, the onset of sedative/analgesic effects could be slowed, or the depth and duration of effects could be diminished or nonexistent. Therefore, allow dogs and cats to rest quietly for 10 to 15 minutes after injection. Repeat dosing has not been evaluated.

Reversible corneal opacity may occur during sedation. An eye lubricant should be applied to prevent corneal desiccation that may result from a reduction in the blink reflex or decrease in tear production during sedation.

Spontaneous muscle contractions (twitching) can be expected in some dogs sedated with Dexvetidine.

The use of Dexvetidine as a preanesthetic in dogs and cats significantly reduces the amount of induction and maintenance anesthetic requirements. Careful patient monitoring during anesthetic induction and maintenance is necessary to avoid anesthetic overdose.

Analgesia resulting from preanesthetic Dexvetidine is dose-dependent, and may not provide adequate pain control during the postoperative or postprocedural period. Additional pain management should be addressed as needed.

Administration of anticholinergic agents in dogs at the same time or after Dexvetidine could lead to adverse cardiovascular effects (secondary tachycardia, prolonged hypotension, and cardiac arrhythmias^{2,3,4}). However, an anticholinergic drug may be administered at least 10 minutes before Dexvetidine for the prevention of the dexmedetomidine-induced reduction in heart rate. Therefore, the routine use of anticholinergics simultaneously with, or after Dexvetidine in dogs, is not recommended (see **Animal Safety**).

The use of anticholinergics in the presence of dexmedetomidine hydrochloride injectable solution has not been thoroughly evaluated in cats. Hypertension and a possible increase in myocardial workload may result from concurrent Dexvetidine and anticholinergic in cats, and the risk/benefit of anticholinergic use should be considered. Routine anticholinergic use is not recommended.

Dexmedetomidine hydrochloride injectable solution has been evaluated only in fasted dogs; therefore, its effects on fed dogs (for example, the occurrence of vomiting) have not been characterized. In cats, there is a high frequency of vomiting whether fed or fasted; therefore, fasting is recommended to reduce stomach contents.

Dexmedetomidine hydrochloride injectable solution has not been evaluated in dogs younger than 16 weeks of age, in cats younger than 12 weeks of age, or in geriatric dogs and cats.

Dexmedetomidine hydrochloride injectable solution has not been evaluated for use in breeding, pregnant, or lactating dogs or cats.

WARNINGS: Keep out of reach of children. Not for human use.

Dexmedetomidine hydrochloride can be absorbed following direct exposure to skin, eyes, or mouth, and may cause irritation. In case of accidental eye exposure, flush with water for 15 minutes. In case of accidental skin exposure, wash with soap and water. Remove contaminated clothing.

Appropriate precautions should be taken while handling and using filled syringes. Accidental splashing (including ocular) exposure, oral exposure, or exposure by injection could cause adverse reactions, including sedation, hypotension, and bradycardia. Seek medical attention immediately.

Users with cardiovascular disease (for example, hypertension or ischemic heart disease) should take special precautions to avoid any exposure to this product. Caution should be exercised when handling sedated animals. Handling or any other sudden stimuli, including noise, may cause a defense reaction in an animal that appears to be heavily sedated.

The material safety data sheet (MSDS) contains more detailed occupational safety information.

To report adverse reactions in users or obtain a copy of the MSDS for this product call 1-888-590-8039.

ADVERSE REACTIONS:

Canine sedation/analgesia field study: In the field study safety analysis, 106 dogs received dexmedetomidine hydrochloride injectable solution and 107 medetomidine sterile injectable solution. Dogs ranged from 16 weeks to 16 years of age, representing 49 breeds. The following table shows the number of dogs displaying each clinical observation (some dogs experienced more than one adverse reaction).

	Dexmedetomidine		Medetomidine	
	Total n = 106	Total n = 107	Total n = 106	Total n = 107
Auscultated unidentified arrhythmias	19	20	1	1
Severe bradycardia requiring treatment	1	1	1	1
Apnea requiring treatment	1	0	1	0
Slow onset of sedation (exceeding 30 minutes)	1	1	1	1
Ineffectiveness (dog standing throughout the study)	3	2	1	1
Severe hypothermia requiring treatment	2	0	1	0
Prolonged recovery	1	4	1	4

The occurrence of auscultated unidentified arrhythmias (some at multiple time points) decreased following the administration of atipamezole hydrochloride.

Feline preanesthesia field study: The preanesthesia field study safety analysis included 192 dogs, between 5 months and 15 years of age, representing 43 breeds enrolled for elective procedures conducted under general anesthesia. The following table shows the number of dogs within a treatment group that showed each clinical sign (some dogs experienced more than one adverse reaction).

	Treatment Groups					
	Propofol n = 32	125 mcg/m ² n = 32	375 mcg/m ² n = 32	Barbiturate		
				0 mcg/m ² n = 32	125 mcg/m ² n = 32	375 mcg/m ² n = 32
Ventricular premature contractions	0	2	0	4	1	0
Severe bradycardia	0	0	1	0	0	1
Tachycardia	0	0	0	1	1	0
Diarrhea	1	0	0	3	1	1
Emesis	4	7	4	2	3	6
Urinary incontinence	0	0	0	0	0	1
Self trauma	0	2	1	2	1	0

Other clinical signs observed in dogs treated with dexmedetomidine hydrochloride injectable solution include decreased respiratory rate and hypothermia.

Feline preanesthesia field study: The field study safety analysis included 242 cats (122 received dexmedetomidine hydrochloride injectable solution; 120 received xylazine), 0.5 to 17 years of age, and representing 19 breeds. The following table shows the number of cats reported with an adverse reaction (some cats experienced more than one adverse reaction).

	Dexmedetomidine hydrochloride n = 122		Xylazine n = 120	
	Vomiting	70	82	1
Urinary incontinence	6	11	1	1
Hypersalivation	4	5	1	1
Involuntary defecation	4	1	1	1
Hypothermia	2	1	1	1
Diarrhea	2	0	1	1
Arrhythmia	1	2	1	1
Corneal ulcer	1	0	1	1
Cyanosis	1	0	1	1
Dyspnea	1	0	1	1

The most frequently observed adverse reaction was vomiting in both fasted and fed cats. Other infrequent clinical signs observed in cats treated with dexmedetomidine hydrochloride included fatigue, anorexia, cystitis, and peripheral vascular disorder. One incidence of dyspnea was reported, 43 minutes after dexmedetomidine administration during an oral examination/dental procedure. Prior to dexmedetomidine, the cat was free of clinical signs, but had a history of asthma and respiratory infection. The cat responded successfully to treatment.

Feline preanesthesia field study: The field study safety analysis included 184 cats (116 received dexmedetomidine hydrochloride; 68 received saline), 0.2 to 16 years of age, and representing 11 breeds. The following table shows the number of cats reported with an adverse reaction (some cats experienced more than one adverse reaction).

Induction Anesthetic	Ketamine				Propofol			
	Saline n = 37		Dexmedetomidine hydrochloride n = 64		Saline n = 31		Dexmedetomidine hydrochloride n = 62	
	Preanesthetic	Saline n = 37	Dexmedetomidine hydrochloride n = 64	Saline n = 31	Dexmedetomidine hydrochloride n = 62			
Apnea		1		1				
Behavioral change								
Corneal injury	1							
Decreased body temperature		4						
Emesis	2	20	1	12				
Fluid in endotracheal tube								
Heart murmur								
Loose stool		2						
Pale mucous membranes		11						
Retching		1						

INFORMATION FOR OWNERS: Due to the rare possibility of delayed onset of pulmonary edema which has been associated with administration of other alpha₂-adrenoreceptor agonists in cats, up to 3 days after use, animal owners should notify their veterinarian immediately if their cat experiences difficulty breathing.

CLINICAL PHARMACOLOGY: Dexmedetomidine is a potent non-narcotic alpha₂-adrenoreceptor agonist which produces sedation and analgesia. These effects are dose dependent in depth and duration. Blood pressure is initially increased due to peripheral vasoconstriction, subsequently dropping to normal or slightly below normal levels. Vasoconstriction may cause mucous membranes to appear pale or mildly cyanotic. This initial vasopressor response is accompanied by a compensatory marked decrease in heart rate mediated by a vagal baroreceptor. The peripheral pulse may feel weak and a transient change in the conductivity of the cardiac muscle may occur, as evidenced by first and second degree atrioventricular blocks. Other arrhythmias may occur.

Dexmedetomidine also decreases the respiratory rate and decreases body temperature. The magnitude and duration of the decrease in body temperature is dose dependent. Dexmedetomidine causes depression of gastrointestinal motility due to decrease in smooth muscle activity, increases blood glucose levels due to inhibition of insulin release, and increases production of urine. Spontaneous muscle contractions (twitching) can be expected in some dogs sedated with dexmedetomidine. Vomiting in cats has been associated with alpha₂-adrenoreceptor agonist central stimulation of the brain.

ANIMAL SAFETY:

Canine safety study: In the multiple dose safety study, dexmedetomidine hydrochloride injectable solution was administered at 0, 1, 3 or 5 times (X) the recommended IV and IM doses on 3 consecutive days to a total of 36 healthy, young beagles. Two additional groups were given a 3X dose of dexmedetomidine hydrochloride injectable solution (IV or IM) followed by three 1X doses of the reversal agent, atipamezole hydrochloride injectable solution, every 30 minutes. This was repeated for a total of 3 days. No deaths occurred during the study.

1X dose group: At the recommended dose, sedation lasted less than 3 hours. During sedation, muscle twitches occurred intermittently, and decreases in temperature, respiratory rate and heart rate were observed in all animals. A slow pupil response to light was seen transiently about 15 minutes after dosing in one of twelve dogs. Second degree atrioventricular (AV) blocks were observed in one of twelve dogs.

3X dose group: At 3 times the recommended dose, the duration of sedation was between two and eight hours. During sedation, muscle twitches occurred, and temperature, respiratory rate, and heart rate decreased in all dogs. The pupillary light reflex was transiently decreased for up to 90 minutes in four of twelve dogs. Vomiting was seen in two of twelve dogs. One dog experienced first and second degree AV blocks; second degree AV block was observed in three of twelve dogs. Elevated concentrations of alanine aminotransferase (ALT) were observed in one dog, without histological changes to the liver.

5X dose group: At 5 times the recommended dose, the duration of sedation was between four and eight hours. Muscle twitches, decreases in temperature, respiratory rates, and heart rates were seen in all dogs. No pupil response was noted in six of twelve dogs (IV) for up to 1.5 hours; decreased transient pupillary light reflex was seen for up to 60 minutes in two of twelve dogs (IM). Vomiting was seen in one of twelve dogs. First and second degree AV blocks were observed in one of twelve dogs. Elevated concentrations of ALT were observed in 3 of 12 dogs, without histological changes to the liver.

Dexmedetomidine hydrochloride injectable solution demonstrated dose dependent effects related to its pharmacology when administered IV or IM to healthy dogs at doses up to five times the recommended dose.

Canine safety study with an anticholinergic: In another laboratory safety study, one of three doses of an IM anticholinergic drug or saline was administered 10 minutes before, at the same time, or 15 minutes after 500 mcg/m² IM dexmedetomidine hydrochloride injectable solution. The anticholinergic drug was given for the prevention or treatment of dexmedetomidine-induced reduction in heart rate. In a crossover design, 18 dogs were used in a total of 72 trials, to evaluate the safety of dexmedetomidine hydrochloride injectable solution used with an anticholinergic drug. Dogs were instrumented for the accumulation of continuous ECG data. The following arrhythmias were recorded during the study (some dogs experienced more than one arrhythmia).

Type of arrhythmia	Number of dogs (of 18)
Second degree AV block	18
Third degree AV block	6
Ventricular escape beats	16
Ventricular premature contractions	14
Idioventricular rhythm	1
Supraventricular tachycardia (SVT) or SVPCs	16
Paroxysmal VT	1
Ventricular bigeminy; SVPCs; pulse alternans	1
Junctional escape beat	1

*Table does not relate arrhythmias to the presence or absence of anticholinergic.

The occurrence of arrhythmias was not related to the presence or absence of the anticholinergic drug. Arrhythmias were transient (although frequent over time in some dogs), returning toward baseline levels within 55 minutes after dexmedetomidine hydrochloride injectable solution. No dogs required treatment related to these arrhythmias, and none of these arrhythmias persisted or adversely affected the overall clinical status of any dog in the study.

Dexmedetomidine hydrochloride injectable solution without anticholinergic: Without the anticholinergic drug, and in addition to arrhythmias, dexmedetomidine hydrochloride injectable solution produced clinically relevant sedation accompanied by a statistically significant reduction in heart rate, respiratory rate, cardiac output, pulmonary arterial temperature, and mixed venous oxygen tension. A statistically significant increase in arterial blood pressure, pulmonary capillary wedge pressure, central venous pressure, and systemic vascular resistance was noted. No dogs experienced hypotension. Dexmedetomidine hydrochloride injectable solution tended to increase pulmonary vascular resistance. Dexmedetomidine sterile injectable solution alone had no statistically significant effect on mean pulmonary arterial pressure, arterial pH, arterial carbon dioxide tension, and arterial oxygen tension.

Dexmedetomidine hydrochloride injectable solution plus anticholinergic: Either of the two higher anticholinergic doses was effective in the prevention or treatment of the dexmedetomidine-induced reduction in heart rate. Anticholinergic (higher doses) given after dexmedetomidine hydrochloride injectable solution caused marked increases in the occurrence of various cardiac arrhythmias, especially second degree AV block. When the higher doses of anticholinergic drug were given at the same time or 15 minutes after dexmedetomidine hydrochloride injectable solution, large increases in heart rate (>0.01) and blood pressure (<0.05) were seen.

Increases were dose related; the highest anticholinergic dose elicited more frequent arrhythmias and larger increases in heart rate and blood pressure. In conclusion, moderate doses of anticholinergic drug given prior to dexmedetomidine hydrochloride injectable solution performed best for the prevention of dexmedetomidine-induced reduction of heart rate in dogs. The routine use of anticholinergics given simultaneously with, or after Dexvetidine, is not recommended.

Feline safety study: In a multiple dose safety study, dexmedetomidine hydrochloride injectable solution was administered intramuscularly (IM) at 1X, 3X, and 5X (40, 120, and 200 mcg/kg) the recommended dose of 40 mcg/kg on 3 consecutive days to healthy cats 6 to 8 months old. A control group received the product vehicle as a placebo (0X). No mortality was observed. The depth and duration of sedation was dose dependent, lasting approximately 2 hours in the 1X group, 2 to 4 hours in the 3X group, and greater than 8 hours in the 5X group. The lowest recorded individual heart rate was 60 beats/minute and occurred in the 5X dose group (2 cats). Cardiac arrhythmias characterized by isolated junctional escape complexes with episodes of junctional escape rhythm were observed during periods of low heart rate or following sinus pauses in all dexmedetomidine dose groups. In most cases the arrhythmia was no longer observed after 1 to 2 hours. Atrioventricular block was not observed. Incidences of arrhythmias were not related to dose; however, more cats were affected by cardiac arrhythmias on the third day of treatment, compared to the first two days of the study. The decrease in respiratory rate, but not the duration, was dose dependent. The rectal temperature decreased in all dexmedetomidine-treated groups, with the lowest temperatures in the 5X group at 8 hours on all three days. Two cats vomited (40 and 120 mcg/kg). Corneal opacity was noted in all dexmedetomidine dose groups, was transient, related to dose and duration of sedation, and was attributed to lack of lubrication with decreased blinking during sedation. Hematology and blood chemistry were unaffected by treatment. Injection site tolerance was good, with mild inflammatory lesions representative of the IM injection procedure. Gross and histological examination of all other tissues did not reveal any abnormalities related to dexmedetomidine hydrochloride injectable solution administration
